

FitBuddy AI — Problem & Opportunity Statement

Phase 1 • Brainstorming & Ideation

Source note: This statement is derived from the supplied project overview and objectives; it is not a report of independent user research.

Project context

- FitBuddy AI is a local-first fitness planning web application that combines a responsive user interface, FastAPI backend, SQLite persistence, optional Gemini-based plan generation, deterministic demo mode, feedback capture, automatic rule-based plan adjustments, a coach dashboard, and JSON REST APIs.
- The project objectives show a need for a practical way to collect a user's fitness profile, goals, schedule, diet, equipment, limitations, and preferences and then turn that information into a weekly fitness plan.

Problem statement

- Users need a structured way to provide personal fitness preferences and receive a practical weekly plan in one workflow.
- A generated plan should not be static: the documented workflow captures feedback and uses that feedback for later rule-based adjustments.
- For a classroom or local demonstration, the solution should remain usable without requiring a live AI service.

Opportunity areas

- Personalized onboarding using profile, schedule, equipment, diet, limitations, and preferences.
- Weekly plan generation with an optional AI path and a deterministic local fallback.
- Feedback-driven refinement so subsequent generation can respond to user feedback.
- Coach/API visibility through summary and feedback endpoints.
- Simple local deployment without a separate Node.js build step.
